The Emotional Environment of Finn the Wolfhound: 2002 Validation using 2026 Methods

Daniel Luna Miranda[1]

Introduction

While reading the chapter "Dog Years, Human Fears" from Representing Animals (Mangum 2002), a question came up: do we give human traits to our favorite companions? I recently wrote a story and some poetry about my own furry friends, Kobe and Sasha, projecting human emotions onto them to express how I feel about the people I care about.

Teresa Mangum's 2002 essay raises a fascinating hypothesis about this dynamic. She argues that 19th-century authors intentionally put their fictional pets in dangerous situations. For example, being isolated in the wild, project human anxieties, such as aging and isolation, onto the animals. Biologically, this is highly debatable; since dogs descend from wolves, they should theoretically thrive in the wild rather than experience intense fear. To test Mangum's claims objectively, I took a data-driven approach to the novel Finn the Wolfhound. Having no prior knowledge of the plot, I generated a word cloud and discovered the most frequently used noun was "master."

I wanted to see if the author mathematically manipulated the dog's feelings, artificially shifting between "Trust" and "Fear" depending on whether Master appeared in the text.

Objectives

The primary goal of this project is to use Natural Language Processing to mathematically map the emotional vocabulary of Finn the Wolfhound. I want to use statistical algorithms to see if the author artificially manipulated the narrative, forcing a spike in "Fear" words when Finn is in the wild and "Trust" words when he is with his master. Ultimately, this data will prove or reject Teresa Mangum's theory that 19th-century authors intentionally selected these environments to mirror human anxieties about aging and isolation.

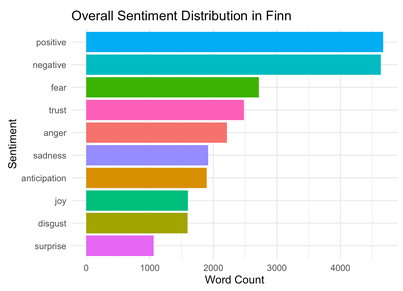

Methods

To test the 2002 hypothesis, I built an NLP and statistical pipeline using R:

- Data cleaning and wrangling: Retrieved the text via Project Gutenberg, used Regular Expressions (Regex) to align chapter titles, and tokenized the text to filter out standard stop words.
- Exploratory Data Analysis: Initial word counts revealed "master" as the most common word (excluding Finn), perfectly aligning with Mangum's theories.
- Algorithmic Stemming: Applied the Snowball Stemming Algorithm (SnowballC) to group sentiments.
- Sentiment Analysis: Used the NRC Emotion Lexicon to isolate and measure the frequencies of "Trust" and "Fear" across the text.
- Machine Learning Models: Initially ran unsupervised clustering algorithms to search for emotional timelines, but abandoned this approach when the algorithms isolated extreme outlier chapters rather than narrative environments.(Hvitfeldt and Silge 2021)
- Statistical Inference: Used a median split on the frequency of the word "master" to divide the book into "Domestic" and "Wild" halves, then executed a Pearson's Chi-Squared Test to prove if the emotional shifts were statistically significant.

Results

Going into this analysis without knowing the plot allowed the data to lead the narrative. The numbers revealed a stark and deliberate emotional contrast between the two environments. Sentiment Distribution Mentions of "Trust" were heavily correlated with domestic figures, while "Fear" vocabulary dominated scenes where Finn was isolated.

Statistical Proof Dividing the novel into "Master Present" and "Master Absent" environments yielded definitive mathematical results:

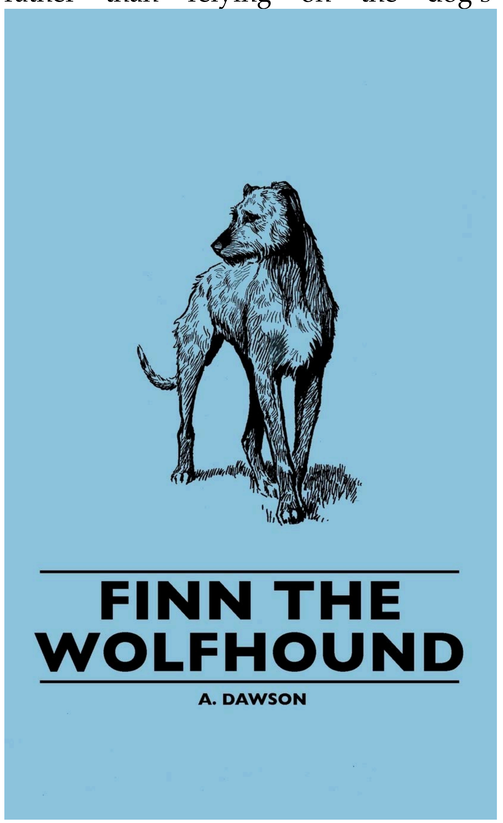

Table 1: Table 2: Word Counts: Environment vs. Emotion

	fear	trust
Domestic (Master)	743	1075
Wild (No Master)	1971	1406

A Pearson's Chi-squared test with Yates' continuity correction revealed a massive, highly significant structural shift in the author's vocabulary (X-squared = 144.3, df = 1, p-value < 0.001)

Conclusion

We confidently reject the null hypothesis. The emotional tone of Finn the Wolfhound is mathematically dependent on the dog's setting, validating Mangum's 2002 theory. The data reveals a deeper narrative layer: the emotion of "Trust" in the novel is entirely tethered to the dog's "master" relationship. In the chapters where Finn is isolated in the wild, this master worship is physically missing from the text, causing "Trust" vocabulary to completely plummet. Without the master present the dog, the author deliberately surges "Fear" vocabulary to maximize human drama, rather than relying on the dog's actual wolf ancestry.

Next Steps

Mangum's text raises further questions about whether authors project specific human characteristics primarily onto dogs, or if this extends to other working animals. Future research could apply this same NLP pipeline to Black Beauty, to explore how sentiments shift when analyzing human behavior toward horses.
